

My Report

Practice message dispatch:

Example:

```
Object subclass: #Shape
  instanceVariableNames: ''.
```

```
Shape >> area
^ 0.
```

```
Object subclass: #Circle
  instanceVariableNames: 'radius'.
```

```
Circle >> initialize
  radius := 5.
```

```
Circle >> area
^ 3.14 * radius * radius.
```

```
Object subclass: #Square
  instanceVariableNames: 'side'.
```

```
Square >> initialize
  side := 4.
```

```
Square >> area
^ side * side.
```

"Test"

Shape new area. "→ 0"

Circle new area. "→ 78.5"

Square new area. "→ 16"

Did the examples work as expected?

Yes, each shape correctly returned its specific area.

What was different between what you expected and what you saw in reality?

At first, I thought that area would always come from the Shape class, but Pharo chooses the method of the actual subclass.

How can you correct your assumptions and how did you find this information?

The correction is to understand that Pharo uses dynamic dispatch (it looks at the concrete class of the object).

I discovered this by running the tests and comparing the results.
